

Trilogy Troubleshooting Guide

Version 1

RP976

Revised: March 23, 2020

This guide is to help the technician better troubleshoot problems on QE and VE models always remember the basics do we have enough waterflow and enough airflow a lot of issues stem from the basics.

| Verifying proper Antifreeze protection in the closed loop. | 27-28 |
| Air locked pumps, Pump flow but Unit does not start, Hot water operation, Noise from the Compressor in the Hot Water mode. | 29 |
| Swapped Thermistors on the WXM board on the water heater. | 30 |
| Dip tube problems, If the elements are not working. | 31 |
| Problems with Setting back temperature in the space. | 32 |
| Zoning setup and problems that can happen. | 33 |
| PVE oil verse POE oil, Sub assembly part numbers. | 34 |
| Catalog data things to know that are not in the IOM. | 35-36 |

How to Retrieve Fault Codes and Sub Fault Codes

Most cause with unit online you and the homeowner will be getting an e-mail with the fault or the WARNING. Be sure to look at the list of faults and warnings so in some cases you may not need to rush right over and check the unit out if it is a warning also you can let the homeowner know it is just a warning and ease there mind you are on their issue.

Faults can be looked up a few ways with the contractor portal, on the thermostat, and with the service tool onsite.

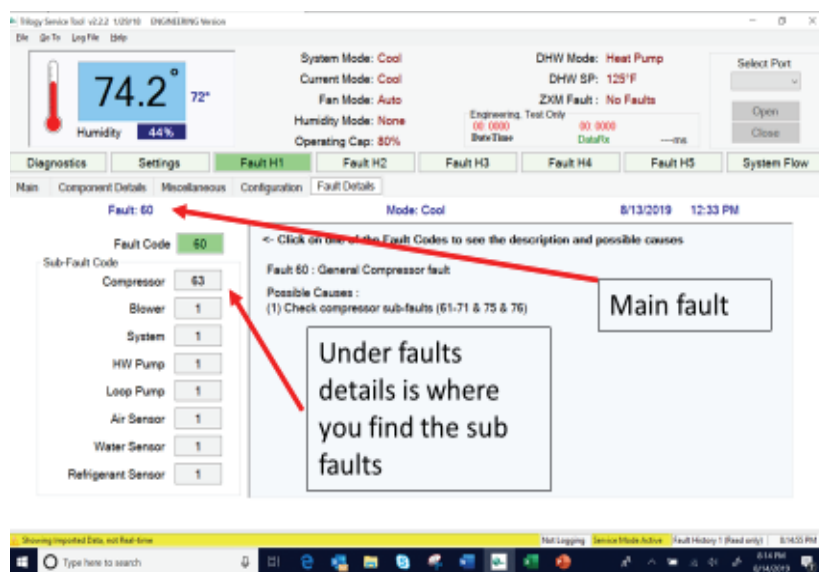

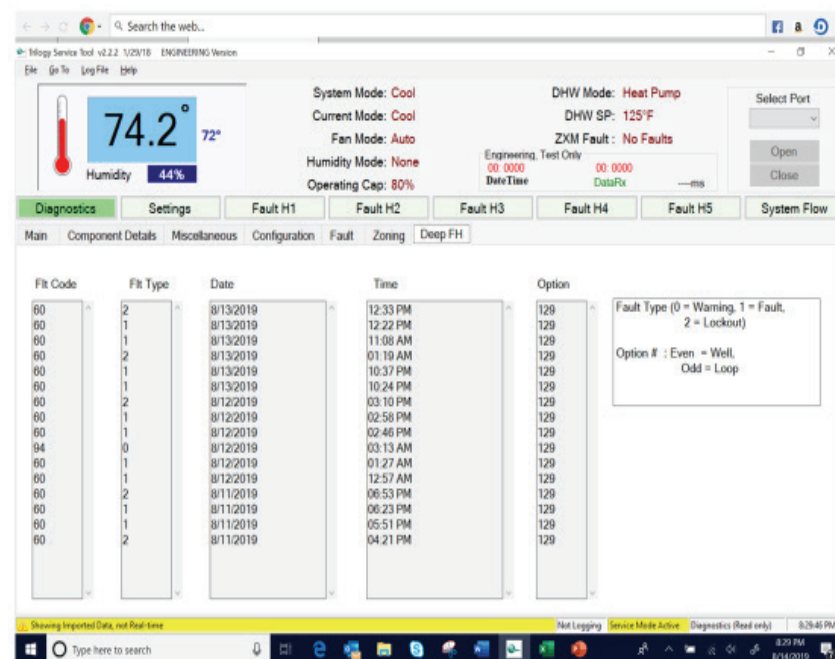

Figure 1 Using the service tool

With the service tool latest version there is a deep fault history which will show even more then the last 5 faults and it will show under fault type if it is a warning or a fault and if it is locked out.

Using the service tool getting sub faults

From the thermostat under settings you can look at fault history on the I Gate thermostat.

Fault details to get Sub Faults.

List of Faults and Warnings

Note: Below the ones in **Green print** are warnings not hard lock outs or faults

Fault code 2 High Discharge pressure

- 600psi

Fault code 3 Low suction pressure

- 95 psi cooling and cooling at hot water 95psi if not antifreeze heating and hot water if set to antifreeze then 50psi in heating and hot water.

Fault code 6 Condensate overflow

Fault code 7 Over under voltage

- 19-32 volts

Fault code 10 ECM blower low RPM

- Bellow 100RPM

Fault code 12 Loss of U2 communications

Fault code 13 Low flow on variable speed pump

- Less then 1gpm

Fault code 14 High discharge temperature

- 0930=239 degrees and 1860=248degrees

Fault code 15 Discharge pressure sensor

Fault code 16 Suction pressure sensor

Fault code 17 Space temp sensor

Fault code 18 Humidity sensor (Warning)

Fault code 19 Low differential pressure

Fault code 20 ECM configuration

Fault code 21 ECM static pressure (Warning)

- Future not used at this time

Fault code 22 Grundfos Flow Sensor

Fault code 23 Grundfos Pressure Sensor

Fault code 24 Leaving air Temperature (Warning)

Fault code 25 High Entering water temperature (Warning)

- 110 degrees or higher

Fault code 26 Low Entering Water Temperature (Warning)

- 22 degrees with antifreeze or 40 degree without

Fault code 27 Low Cabinet Temperature (Warning)

Fault code 28 Low loop Pump Feedback (Warning)

Fault code 29 Loop Pump Low Voltage (Warning)

Fault code 30 Loop Pump Locked Rotor

Fault code 31 Loop Pump Low Voltage

Fault code 32 Loop Pump Sensor

Fault code 33 Hot Water Pump Feedback (warning)

Fault code 34 Hot Water Pump Voltage (Warning)

Fault code 35 Hot Water Pump Locked Rotor

Fault code 36 Hot Water Pump Low Voltage shutdown

Fault code 37 Hot Water Pump Sensor

Fault code 38 Suction Temperature sensor

Fault code 39 Discharge temperature Sensor

Fault code 40 Entering Hot Water Temperature sensor

Fault code 41 Leaving Hot water Temperature sensor

Fault code 42 Air Coil Liquid Temperature sensor

Fault code 43 Air Coil Vapor Temperature sensor

Fault code 44 Water coil Vapor Temperature sensor

Fault code 45 Water Coil Liquid Temperature sensor

Fault code 46 Hot Water Liquid Temperature sensor

Fault code 48 Lower Hot Water Tank Sensor (Warning)

Fault code 49 Upper Hot Water Tank Sensor (Warning)

Fault code 50 Reduced Hot Water Setpoint (Warning)

Fault code 51 High Suction Pressure Limiting (Warning)

- 170psi

Fault code 52 Low Suction Pressure Limiting (Warning)

- 106 psi with no antifreeze 61 psi with antifreeze has to see for greater 120 sec.

Fault code 53 Low Discharge Pressure Limiting (Warning)

- 186psi cooling and 236 psi heating

Fault code 54 Loss WXM Communications

- Will not interrupt heat and cooling operation

Fault code 55 WXM High Temperature

Fault code 56 Reduced Hot Water Heat Exchanger Performance (warning)

Fault code 57 Low Discharge Super Heat (warning)

Fault code 58 Low Suction Super Heat (warning)

- Less than 4 degrees for more than 10 mins

Fault code 59 High Suction Super Heat (warning)

Fault code 60 General compressor (Check sub faults 61-74)

Fault code 61 High Temp shutdown

Fault code 62 High current at startup

Fault code 63 High current at shutdown

Fault code 64 High DC voltage at shutdown

Fault code 65 Current sensor warning

Fault code 66 Heat sink thermistor error

Fault code 67 Current sensor error

Fault code 68 Lack of inverter communication initiation

Fault code 69 Low voltage shutdown inverter

Fault code 70 Power supply sync warning

Fault code 71 Converter over current shutdown

Fault code 72 Compressor Current (Warning)

Fault code 73 Heat Sink Temperature (Warning)

- 201degrees

Fault code 74 Inverter Current (Warning)

Fault code 75 Lack of MIM communications

Fault code 76 Low voltage

- Between the MIM and the inverter board

Fault code 77 Low Leaving Air Temperature (warning)

- Future not used currently

Fault code 78 High Leaving Air Temperature (warning)

- Future not used currently

Fault code 79 Low Sub Cooling (Warning)

- Less than 1 degree for more than 10 mins

Fault code 80 ECM Blower Fault (Check sub faults 81-91)

Fault code 81 ECM lost rotor fault

- Possible issue set screw on blower wheel

Fault code 82 ECM current trip fault

Fault code 83 ECM temperature limit

Fault code 84 ECM Locked rotor

Fault code 85 ECM high voltage

- if higher than 20% then nominal 240V

Fault code 86 ECM low voltage

- if lower than 20% of nominal 240V

Fault code 87 ECM Blocked Inlet

Fault code 88 ECM power Limit

Fault code 89 ECM Temperature limit (Warning)

Fault code 91 ECM Power configuration (Warning)

Fault code 93 Heating check valve (warning)

Fault code 94 Cooling check valve (warning)

Fault code 95 Hot water check valve (warning)

Fault code 96 Low Hot water delta T (warning)

Fault code 97 Pressure sensor error

Fault code 98 Loop Flow at idle

- greater than 1 GPM

Fault code 99 Mode Transitions Timeout

- time to reach 400psi is 10 minutes

Fault code 100 Low loop pressure (Warning)

- 5psi

Fault code 200 Loss zone damper power

- Secondary transformer also check fuse on the ZXM board

Fault code 201 Thermostat configuration (warning)

Fault code 202 Loss of zone thermostat communications (warning)

Fault code 203 Loss ZXM communications (ZXM is the zone board)

Fault code 205 ZXM configuration

Some Fault and Warning Details

Fault #2 High Pressure lockout

This occurs when the high side reaches 600psi

Typical reasons this may happen

In Heating not enough airflow caused from dirty filter or other blockages

In Cooling from not moving water or enough on the loop side could also be air in the loop causing the pump to cavitate

In the Hot water mode or Cooling and hot water mode from not moving enough domestic hot water or air locked pump. Also, the default HW delta T is 8 degrees I would not raise this as that can lead to HP faults especially in the hot water setpoint is higher than 125 degrees

Fault #3 low pressure lockout

This occurs when the low side hits 95 psi in cooling, Cooling Hot water, heating with no antifreeze.

If the unit has proper antifreeze protection it needs to be between 10 and 12 degrees freeze protection and the unit is configured for antifreeze, then the low side cutout is 50 psi in heating and in hot water mode.

Possible causes.

Not enough antifreeze as stated above 10-12 degree protection is needed. **Please verify it with hydrometer or digital refractometer.**

Heating delta T set to high this will cause the leaving water leaving the braze plate heat exchanger to be even colder and the Water coil liquid line will be colder there by dropping the suction pressure as well.

Typical setting is 6 degrees default if lowest EWT in the winter drops to 30 degrees or maybe slightly lower do not raise it above 6. Range 4-12 .

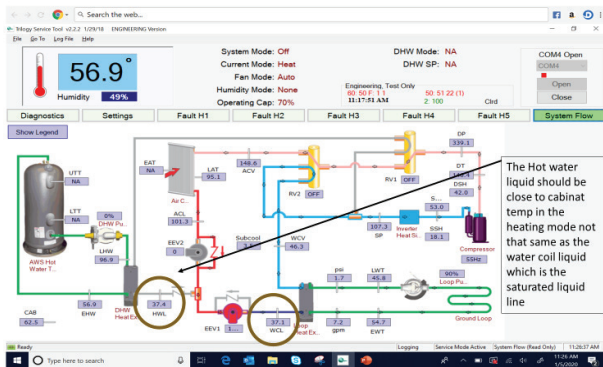

Air trapped in the braze plate we have seen cause nuisance low pressure lockouts. Downflow models especially with the braze plate being at the top of the unit.

Not having proper EEV operation can also cause low pressure faults the EEV maintains suction superheat and uses the suction transducer to calculate suction saturation temperature and uses the suction line thermistor to read suction line temp to calculate this so if either of these are not reading accurately this can cause low pressure lockouts as well as capacity issues. EEV #1 in heating (Lower Valve) EEV#2 in cooling (upper valve) Software version 2.05 on the EXM board and higher has changes that have quicker reaction to low suction pressure conditions having EEV 1 react quicker. (also see section on how to check EEV's)

Have also seen RV#2 sometimes not sliding all the way over cause the unit to pump down and will get a low-pressure lockout fairly quickly. (also see section on troubleshooting 4 way valves)

In the cooling mode if the entering air temp is too cold it can cause low suction pressure faults if return air temp is below 70 you will need to raise the minimum and the maximum cooling airflow. The lowest this unit can run down to reliable is 67 degrees return air temp below that there is a good chance of low suction pressure faults.

Also a leaky hot water check valve can cause low suction pressure faults some time it may be random faults and then it will stay high enough on the suction side to run. How you can start to see this issue is the Hot water liquid line will be much colder than what it should be in the heating mode or cooling mode this will be an indication that the Hot water check valve did not seal well and is acting like a metering device. On a cold start up this can be a significant charge in the hot water circuit so it will be for a short while like it is low on charge and then may lock out especially when not set to antifreeze in those applications. THIS COULD ALSO UNDER LOW LOOP TEMPS FREEZE THE HOT WATER HEAT EXCHANGER IN THE HEATING MODE See screen on next page.

In this screen shot normally when the check valve is not leaking the HWL line in the heating mode is around the cabinet temperature this is another clue that this valve is leaking.

Fault #19 Low Refrigerant pressure differential

When there is less than 20psi difference from suction pressure and discharge pressure and if suction temperature is greater than 10 degrees. The compressor will keep trying to speed up to get out of this if it does not it will time out in 2 minutes after 3 of these in a row it will lock out.

This could happen if a RV valve did not properly shift causing the unit not to build pressure difference and the suction temperature could be high. (look at Troubleshooting RV valves)

Faults #38-#49 these are temperature sensor faults.

These you should look up which one it is referring to and then verify the thermistor using the chart bellow clamp on with a calibrated sensor next to the thermistor and then measure the resistance of that sensor if outside of 10% of the chart then replace the sensor. (See pics on right) You will need thin pin leads for your volt meter to get into the ends of the thermistor plugs

Table 4: Nominal Resistance at Various Temperatures

| Temp (°C) | Temp (°F) | Resistance (kOhm) | Temp (°C) | Temp (°F) | Resistance (kOhm) |
|-----------|-----------|-------------------|-----------|-----------|-------------------|
| -17.8 | 0.0 | 85.41 | 55 | 131.0 | 2.99 |
| -17.5 | 0.5 | 84.16 | 56 | 132.8 | 2.88 |
| -16.9 | 1.5 | 81.43 | 57 | 134.6 | 2.77 |
| -12 | 10.4 | 61.70 | 58 | 136.4 | 2.67 |

| 21 | 69.8 | 11.94 | 91 | 195.8 | 0.89 |
| 22 | 71.6 | 11.42 | 92 | 197.6 | 0.86 |
| 23 | 73.4 | 10.92 | 93 | 199.4 | 0.84 |
| 24 | 75.2 | 10.45 | 94 | 201.2 | 0.81 |

Warning #57 Low discharge Superheat.

Have seen this warning a few times can happen in season changes such as end of the heating season going into cooling will usually have a colder loop which will drop the head pressure down in turn the discharge Superheat can be low. 18 degrees is the min number of DSH to flag this warning.

Verify discharge thermistor is reading correctly and is mounted well to the compressor discharge line also verify discharge pressure sensor is reading correctly if the thermistor checks out. Also need to verify the suction line thermistor and the WCV and or ACV thermistors are reading correct as well as the suction transducer if they are off that can throw the SSH off and drive the DSH to be off as well.

Occasionally in northern climates with cooler loops in the cooling mode you may need to increase the min capacity to 40% from 30% has helped.

Warning #53 Low discharge pressure warning

This can occur when going from the heating season to the cooling season and loop temps are usually a bit low in the 40-50 degree EWT this will reduce the head pressure.

Sometimes increasing the cooling delta T in a northern climate can help make this go away default is 10 degrees increasing it to 12-15 degrees usually is enough to get past this period of time.

Fault #54 Loss of WXM communications

This occurs when there is a loss of communication on the WXM board usually a wire connection between the EXM board and the WXM board on the water tank.

Tug on all 4 wires between the two on the EXM you will have the wires doubled up from the thermostat or the ZXM (Zone Board) which sometimes is tough to have all tight under the terminal strip. NO SPLICES

Warning #56 Hot Water heat exchanger reduced performance

The QE units when making hot water look at the first 4 times it makes hot water and looks at the heat exchanger temps and hot water temps and if after that the heat exchanger temp difference is greater then 5 degrees this message will flag.

This could occur when the heat exchanger is getting fouled and may need cleaned.

This can be reset by toggling the dipswitch number 6 off then back on.

Fault #60 General compressor fault

You must get the sub fault as there are several sub faults here are some of the ones we have seen and what to look for.

62 and 63

Are high current and start up or shutdown there is a kit developed that has resolved most of these faults as they were not real just electrical noise on the inverter board Part#S11S0192N01

If you get this and you have already installed this kit (Units built in 2019 or later have this kit installed from the factory) Then it may be a real fault and current will need to be measured and maybe there is a compressor issue board issue you will need a AMP clamp that can measure peak amps (Inrush) because it will be to quick to just see it on the amp meter. If you measure high amps (1860=28.5 0930=21.4) them next OHM the compressor windings at the compressor need a good volt meter that is true RMS If it checks out then change the inverter board and then re check amp draw. I would install a new inverter board with one of these faults before ever replacing the compressor also be sure there is a surge protector on the unit as well

Sub fault 68

Is loss communications with the MIM board check the lights on the MIM board they should be flashing

Check communication at the MIM board:

- At power-up, both RED and GREEN LEDs should flash rapidly for a few moments while communications are being established. Once communication is established, RED and GREEN LEDs will each flash at 5 second intervals, indicating that MIM is powered, and in communication with the EXM and inverter boards, and that the inverter board has been initialized and is ready for operation.

- If RED LED remains ON continuously, MIM is unable to communicate with Inverter.

- If GREEN LED remains ON continuously, MIM is unable to communicate with EXM.

MIM LED Conditions Fault RED LED Status GREEN LED Description ON - MIM powered but no inverter communication - ON MIM is powered but no EXM communication FAST FLASH - MIM communicating with inverter but initialization not complete - SLOW FLASH MIM communicating with EXM (GOOD!) SLOW FLASH - MIM communicating with initialized inverter (GOOD!) OFF OFF MIM not operational If no inverter communication has been verified, replace the Inverter or MIM board (inverter is the most likely problem). If communication has been verified, proceed to next step.

| MIM LED Conditions | | |
|--------------------|------------------|--|
| Fault RED LED | Status GREEN LED | Description |
| ON | - | MIM powered but no inverter communication |
| - | ON | MIM is powered but no EXM communication |
| FAST FLASH | - | MIM communicating with inverter but initialization not complete |
| - | SLOW FLASH | MIM communicating with EXM (GOOD!) |
| SLOW FLASH | - | MIM communicating with initialized inverter (GOOD!) |
| OFF | OFF | MIM not operational |

If no inverter communication has been verified, **replace the Inverter or MIM board** (inverter is the most likely problem). If communication has been verified, proceed to next step.

Voltage Checks on the MIM Board

| | | |
|-----|---------------------------------|---------------------------------------|
| ALL | Faulty 5 V power supply on MIM | Check C and OUT for 4.75-5.25 VDC |
| ALL | Faulty 15 V power supply on MIM | Check GND and 15V for 14.25-15.75 VDC |
| ALL | Faulty 18 V power supply on MIM | Check GND and 18V for 17.50-19.00 VDC |

When doing voltage checks you will need thin pin leads for your volt meter see next

When replacing the inverter board please watch the video online . Prior to heading to the jobsite and turn power off and wait min 20 minutes before going near the inverter board.

Sub fault 64

High DC Voltage happens when there is 400 volts DC at the inverter board. Verify in coming voltage is correct if within range then replace the inverter board

Sub fault 69 low voltage shutdown

This occurs when there is 340 Volts DC or less be sure in coming voltage is within spec (197-253) if incoming voltage within range then replace the inverter board. I have seen some cases when not over 350V DC the compressor not start.

Sub fault 72 High compressor current

This occurs when the compressor current hits or exceeds 28.5 amps (1860 model) or 21.4amps (0930 model) Res set unit and try to start the unit again with amp clamp measuring max amp draw see if you measure something close to the readings listed if the fault reoccurs if so compressor needs to be replaced. In some cases, the inverter board was also damaged when this high amp draw happens and the inverter board may need to be replaced as well I would recommend having one on hand when replacing the compressor under this circumstance.

Sub Fault 74 High Inverter current

This occurs when the current hits or exceeds 28 amps on (1860model) or 20 amps on (0930 model) If this fault occurs measure compressor **max amps (see pic)** if it is bellow 28amps on 1860 model or bellow 21amps on 0930 model replace the inverter board if the fault re occurs upon trying to re start the unit. Must have a good amp clamp meter that can read inrush current like the one in the picture that shows 13.18amps well below the max allows amps for an 1860 model.

Another test that can be done is turn the power off to the unit wait for power to discharge from the inverter board MIN 20 MINUTES then remove the compressor leads from the inverter board (take note where each color of lead lands on the board U V W then re-start the unit (obviously the unit will not start since compressor leads are not attached) if the inverter board is drawing high current it will still do this without the compressor attached.

Inrush Current On a QE1860 13.18 amps on startup in cooling manual mode.

Surge Protection : HVAC Surge Protection

AG3000 | HVAC Surge Protective Device

Fault code 87 Blocked air inlet warning.

This occurs under high static conditions when the ECM blower motor is near peak RPM when the motor is 1250RPM this occurs operation will not be interrupted but this flag will go out on the thermostat and e-mail warning until capacity and blower speed are lowered to go below 1250 RPM.

We have seen this in some cases where a unit such as the 1860 model is being used on existing ductwork that can not handle the max airflow and this can cause the warning.

Options to correct would be limit the units max capacity or increase the duct work to handle the airflow and capacity needed to support the structure.

I would suggest measuring both supply and return static pressure to determine which one or both is the higher static pressure so you can add to the side with the highest static pressure to bring it down to a more accepting level.

(Obviously a extreme dirty filter or adding a second filter can also cause this condition)

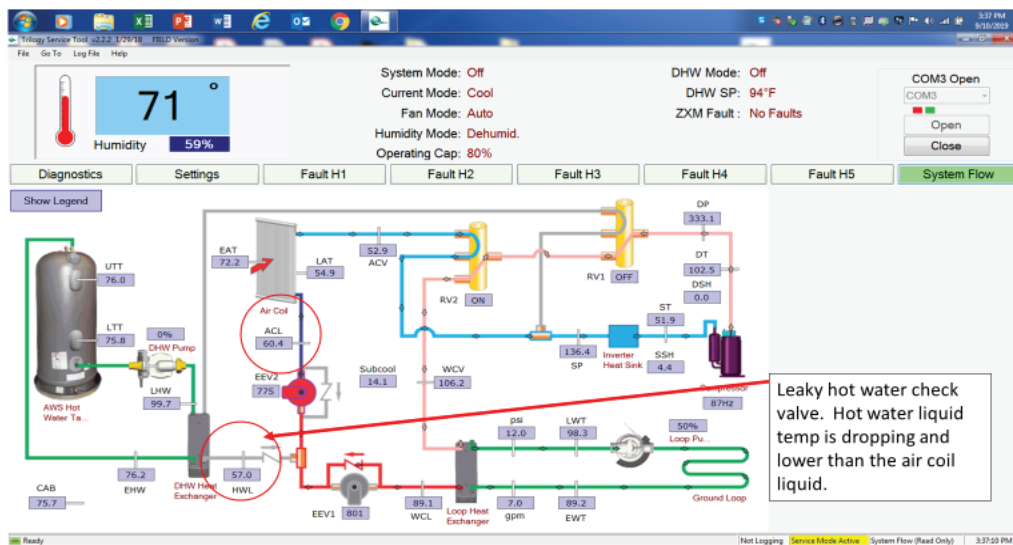

I would not install one of these QE/VE units with out a good Surge protection device

(Example abovedoes not have to be this one) I have seen many times problems with the inverter board Code 60 faults and after installing a surge protector the problems go away. Mike Hammond ClimateMaster.

Fault #93-#95 leaky check valves

(See section on checking for leaking check valves) This can also sometimes look like the unit is under charged as refrigerant is leaking through the check valve and pooling in the un used section of the unit there by subcooling numbers will be lower and Superheat will be high and EEV positions will be at or near max open position which is 1040 steps. Best way to check this is to run the unit in manual mode using the service tool and watch the “system Flow” screen it will really help visualize what is happening.

Hot water check valve is leaking a small amount the hot water liquid line should be around 75 degrees (like the cabinet sensor) under these conditions. So the check valve leaking this small amount is acting like a metering device.

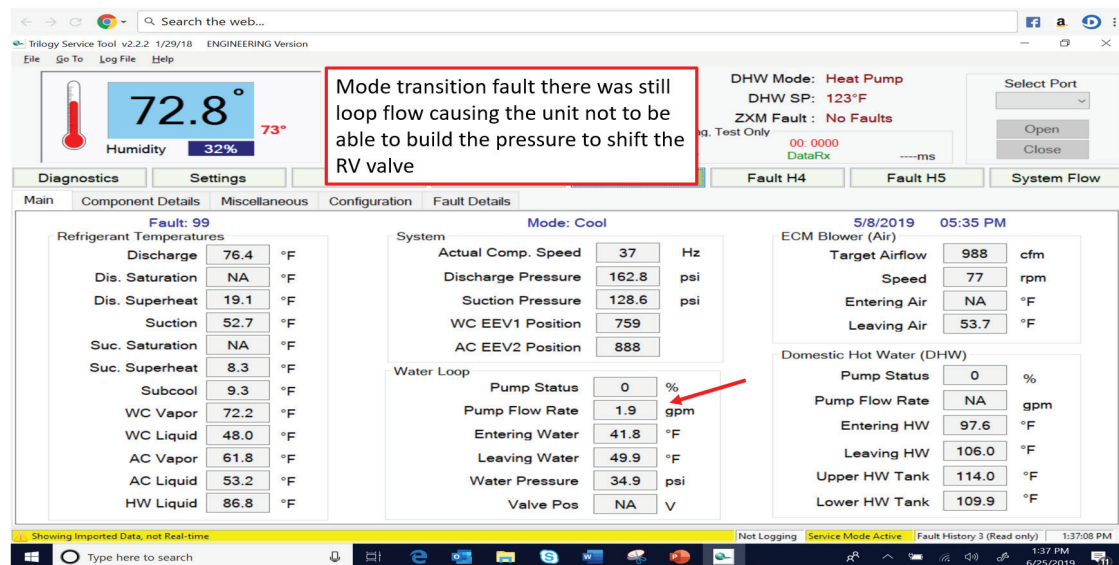

Fault #97 Pressure calibration fault

This occurs when the unit is off and ready to start up and the difference in pressure from the discharge sensor and the suction line sensor is 12psi or greater (under normal operation it is 25 psi when in the service mode operation)

This can occur for instance when the unit is say heating hot water and then fully satisfy and shuts down and then is a short order gets say a heating call it may not have fully equalized pressure default ASCD is 3 minutes range is 2-8 minutes. In most cases this fault can be eliminated by increasing the ASCD to a higher time like 8 minutes. If you have increased the anti short cycle time and this is still occurring check both pressure transducers with a set of refrigerant gauges (Please calibrate the gauges first)

Fault #99 excessive mode transition

This occurs when switching between modes and a 4 way valve needs to shift the unit needs to build 400psi head pressure to be sure to shift the valve this is accomplished by removing flow to the condenser for instance in heating mode will remove airflow to achieve 400psi. In cooling the loop pump will stop (if there is a external pump running may not be able to build head pressure or a stuck open loop pump check valve) the unit will keep ramping the compressor speed during this time trying to increase the head pressure the lockout will occur after 10 minutes once faulted it will wait a ASCD delay and then re start if after 3 in a row occur then it will go into a hard lockout Also external applied accessories such as a ERV or HRV can cause this if there is air moving through the air coil when it is trying to build head pressure See example below

Verifying Grundfos flow and pressure and temperature sensors.

Temperature check.

With unit off go into service mode just run just the pump to 90% speed let it run for 5 minutes then compare on the screen the EWT and the LWT are they reading the same within a degree or less? If so that's good if they are not and over a degree difference next using a calibrated pocket thermometer insert it into the Water In PT port compare that to the EWT on the screen? Next do the same with the LWT which one is off? You can replace this sensor

Another option to replacing the sensor would be for example if the LWT was off 2 degrees (LOW) and the loop heating delta T is set to 6 degrees the real delta T is 8 there by this could under some circumstances

cause low pressure lockouts. You could lower using the service tool the heating delta T to 4 degree now the actual would be 6 degree. Just a option

When the sensor is bad it usually read s ridiculous high number like 222 degrees.

Pressure on the DPD sensor

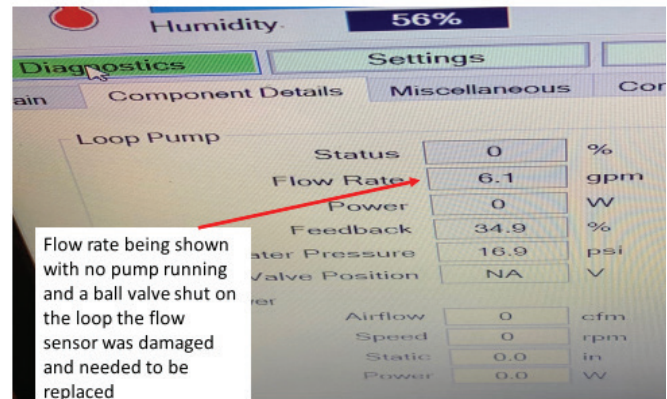

On the leaving water line behind the pump warning 100 is when the sensor is reading at or bellow 5 psi with the pump off what is the static pressure on the screen is service mode? With a pressure gauge with a PT needle insert in one of the ports are they close? (There could be some calibration difference) If there is a huge difference then the DPD could be off and the sensor needs to be replaced. (Note when the pump runs the DPD pressure reading will keep dropping as the pump increases in speed this is on the suction side of the pump. These

pumps need a minimum of 5 psi to be sure they do not cavitate which can lead to pump failure or other lockouts.)

Flow on the VFD sensor

Which is on the entering water line just under the pump in the unit if damaged may not be reading a flow at pump speeds under 50%. This can be tested by under service mode run just the loop pump at say 30% do you then see under diagnostics a loop flow rate? If not then the sensor is bad and will need replaced. A temporary thing that can be done is to configure the unit to parallel pumping this will run the pump to a minimum of 50% which when the pump is 50%-90% it will calculate its flow rate based on the feedback signal from the pump

These sensors read two things temperature and either loop pressure (DPD) or flow rate (VFD) if both are not showing up and you replace the sensor and it is still not showing up the problem could be in the harness to the EXM and there are two of them there is a short 4 inch one from the sensor to the main harness part number (11B0039N01)

Grundfos Flow & Pressure Sensor

The sensors have changed from Grundfos physically they look the same but they are different new part numbers are 17B0078N01 for the DPD sensor and 17B0079N01 for the flow sensor you will also need to update or change out the EXM board to a version 2.07 the communication between the sensors and the board is different so the new sensors **WILL NOT WORK ON OLDER VERSIONS OF THE EXM 1-1-2020**

Troubleshooting EEV valves

On QE models there are two EEV valves on VE models there will just be one EEV.

The job of the EEV is to meter refrigerant into the evaporator and maintain a certain suction superheat most causes around 10 degrees will vary check operating chart in the IOM.

The Carel EEV that ClimateMaster uses in these units range from 0-1040 steps min. operating position is 109 steps but the valve can be driven to completely closed in a QE unit to prevent refrigerant flow.

So when troubleshooting knowing that full open is 1040 steps helps for instance if we have a high superheat number and the valve is fully open we know the evaporator is starving for refrigerant.

Another thing the valve may show its at 1040 steps is it really fully open? With manual operating knob we can verify EEV movement. 19 turns from full open to full close so each turn is approx. 54 steps. Some rare cases a valve was stuck and moving it back and forth with the manual drive knob freed it and it worked afterwards.

Is the problem in the power head or the valve itself? We can swap power heads on QE models to see if we have a faulty power head. Be sure to mark them so you can return them to the correct spot See Pic below

We can also swap EEV 1 and EEV 2 positions on the EXM if we think maybe it's a problem on the EXM and switch modes. (Note may need to remove leads on the RV valve to prevent actual mode change heating to cooling)

Check Valves EEV's less power head

EEV #1 is on the bottom and #2 is on the top on QE units.

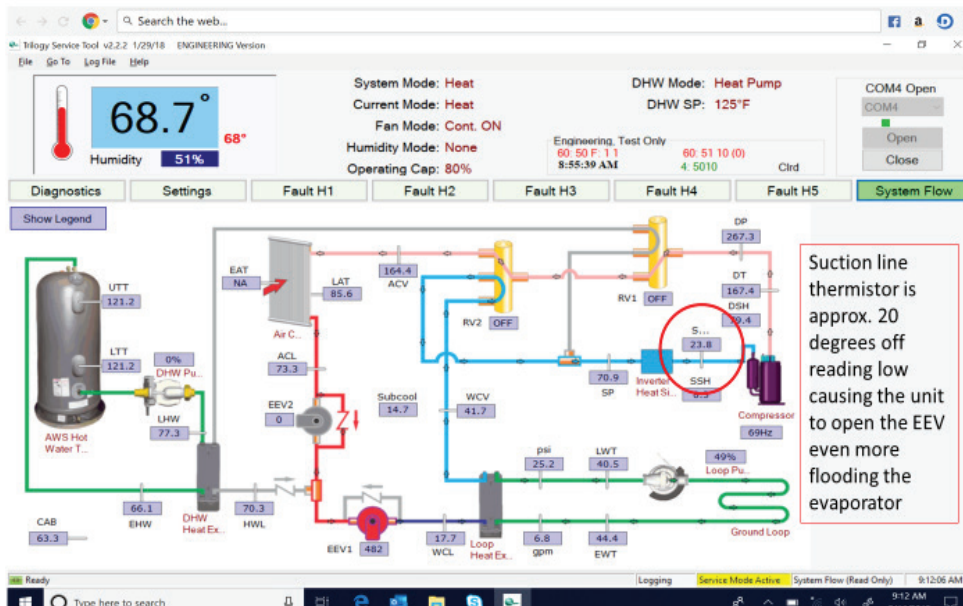

Power head removed and you can see it is a short plug to exchange when swapping to verify if one is bad on a QE model.

From fully closed or open it takes 19 full turns to go open or closed depending where you started you will be able to feel when the valve is fully open or close the magnets in the manual tool can no longer move the steeper motor inside the EEV.

Troubleshooting 4 way valves (reversing valve and hot water diverting valve)

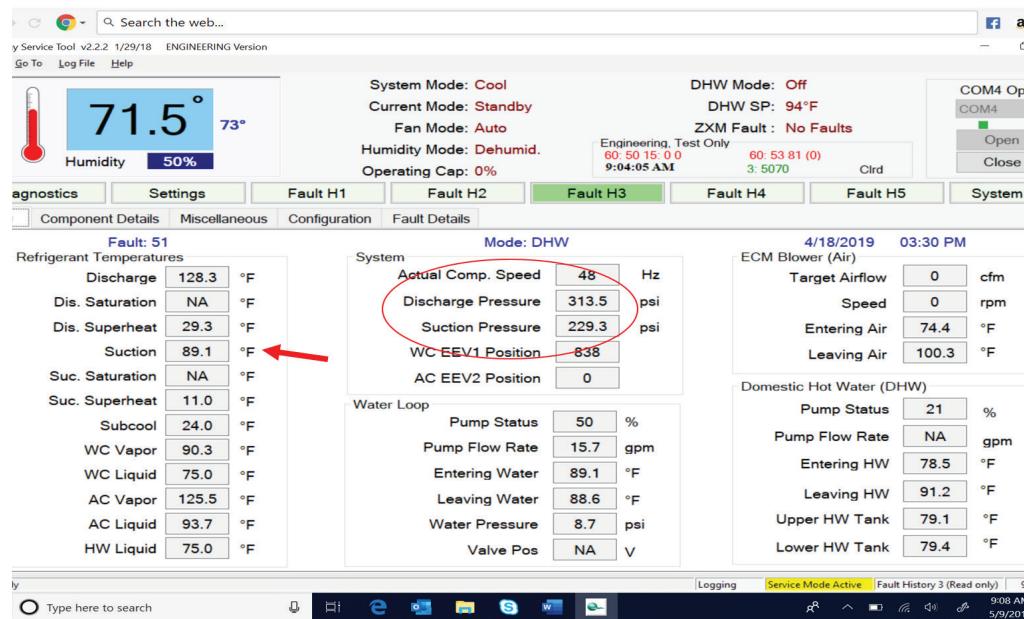

There have been some cases with the hot water diverting valve (See Picture) where it does not shift all the way and the unit can lock out on different faults depending on where the unit was before this valve not moving all the way. For instance if the unit was in Hot water mode and in transition to cooling mode the unit actually switches RV#2 off (Heating mode) and shuts the blower off to build head pressure (400psi) when this happens it switches RV1 and RV2 at the same time if RV1 does not move all the way there may not be enough pressure to move RV2 in the cooling position causing the unit to pump down and lock out on low suction pressure (95psi) When this happens there can also be a loud harmonic sound from the refrigerant velocity.

In other cases RV1 not shifting all the way will leak refrigerant in a circuit not used in that mode causing the unit to be low on charge in the mode it is trying to run in and in most causes as it runs you can see the subcooling numbers dropping and the suction Superheat rising and eventually locking out on low suction pressure in most cases.

To help diagnose what is going on a simple touch test goes a long way see picture bellow describing what lines should be warm hot or cold in the various modes see pictures

Once you find out what valve you need to try and exercise that valve back and forth to see if you can free it up last resort is replacing that valve. Using the service tool can really help in this since we can shift on the fly under manual mode.

AC Renew has worked many times if the valve is sticky but still moves and is worth a try.

Checking the inverter board

The following pictures and descriptions will show and explain checking the inverter boards Transistors you will need to perform the following 12 resistance checks and all should show a resistance value if any are open then the board needs to be replaced. P2 and N2 are the connections where the off board capacitor are tied into the inverter board.

Positive lead on P2 check Negative lead to U,V,and W

Positive Lead on N2 check negative lead to U,V,and W

Negative lead on P2 check positive lead to U,V,and W

Negative lead on N2 check positive lead to U,V, and W

Checking positive lead to N2 and negative lead to V

Always first check the resistance of the test leads so that it can be subtracted from what you measure on the board.

Checking Positive to P2 and negative to U

Checking negative lead on P2 and positive lead on V

Bad board if one of these checks shows open no resistance

Very important that the lead from the positive side attaches to the P2 terminal on the inverter board and the negative side to the N2 or the above can happen to the inverter board.

This can also happen if the MIM board is damaged.

Checking the compressor

See pics bellow on verifying the compressor

All 3 should be the same resistance.

.3 for the 1860 and .58 for the 0930 @68 degrees.

Using a Megameter the compressor windings should all be 200 Meg ohms or greater

Checking the off board capacitor

How sizing can affect the operation of the unit.

On the QE units if hot water modes are being used proper sizing is critical to the hot water production if the unit is put in to big of a load it may make little to no water with the heat pump and have to use the back up elements. Using GeoDesigner after performing a manual J load calculation is a must to know how the unit is going to perform see bellow two examples one being to large of a load the other being a good load for a QE1860 model. See GeoDesigner example below.

Example project in Champaign IL

The Below Examples may not be the same in all areas of the country you must perform a manual J load on your house you are working on and run it threw GeoDesigner and look at the Operating Bin Data to see how it looks.

Heat load for the above was 81,540 and cooling load of 47960

Notice is loop gets colder to get the same capacity the compressor speed goes up in this case 104 HZ

This example shows shortening the vertical loop 100' it dropped the EWT and increases compressor speed to still achieve the heating capacity.

Hot water production from the GEO stops below 12 degrees outside not good customer will be un happy

The 0930 in this heavy heat load has 2,040 hours running over 60HZ compressor speed not good.

This example above had a heat load of 40,245 and a cooling load of 26,980 the 0930 is running hard in these conditions and hot water capacity from the GEO is limited.

This is like my car speedometer says 120MPH so why cant I drive there all the time the car wont last well the same for the GEO in this scenario the customer will not see as good of savings and the life of the unit will be shortened.

Using the same loads as the above 0930 example but using a 1860 and limiting its max capacity's this would be a much better fit.

1860 limited cooling and heating capacity

The screenshot shows the GeoDesigner T software interface. The main window is titled "GeoDesigner T" and contains several panels. The "ClimateMaster System" panel on the left shows "QE 1860 Q-Mode" selected. The "Capacity Limits" panel shows "Max" at 42000 and "Min" at 18000. The "Geo Source Selection" panel shows "Vert 1 U-Tube - 0.75\" selected. The "Auxiliary Heat Selection" panel shows "Electric Duct Heater" selected. The "Auxiliary Heat Operation Mode" panel shows "Supplement Heat Pump" selected. The "Water Heater Selection" panel shows "Gate Smart Tank" selected. The "Soil Selection" panel shows "Average Rock" selected. The "Analysis" panel on the right shows the following results:

Verifying antifreeze levels

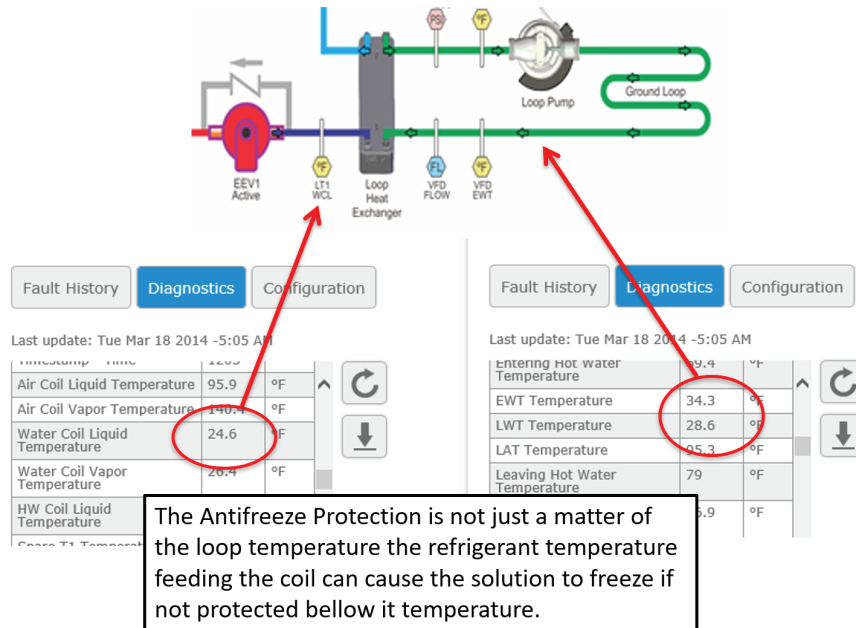

These units use braze plate heat exchangers and the proper antifreeze levels are extremely important or braze plate failure will occur.

Freeze protection should be between 10-12 degrees remember the refrigerant in the braze plate is always colder than the loop fluid right next to it (see braze plate cut picture)

Not having freeze protection in the ranges mentioned above can cause nuisance low pressure lockouts in the heating and hot water modes often many other things are tried and many service calls before the antifreeze level is looked at and then verified or corrected this should be one of the 1st things verified when getting a low suction pressure fault in heating or hot water modes. See pic below of relationship of water temp and refrigerant temp.

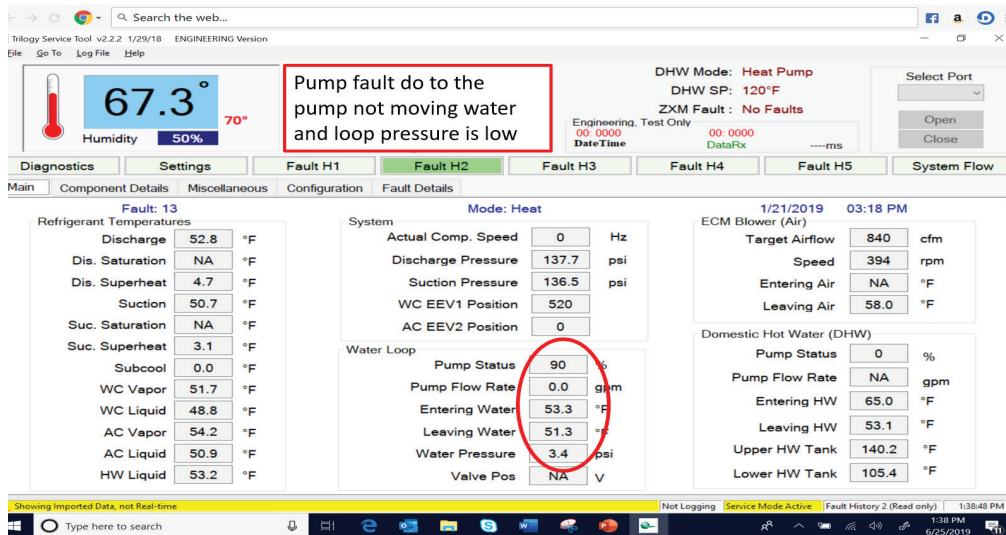

Braze plate cut away shows then passage ways refrigerant and water are close together and proper filtering of the loop fluid is very important you do not want this heat exchanger to be the filter.

Example Test using a digital refractometer from Misco great tool and worth the investment highly accurate and temperature compensating.

Air locked pumps

This can happen when flushing on the closed loop was not completed properly (see video on website) and on the hot water side when not proper burping of the heat exchanger this will take more then a typical desuperheater so provide in the piping a proper way to remove the air.

PUMP FLOW ISSUE that does not let the compressor start

We have seen a few units get hung up and there is no fault or warning with older software versions of the EXM older then 2.05. What happens is the pump starts and there is a low flow but not low enough to trigger a low flow fault but not over 2.0GPM for the compressor to start. Updating the EXM software will not let this happen again in most cases just turning the unit off and back on gets the unit out of this condition and the unit will run until you can update the EXM.

HOT WATER

We have seen on especially down flow units since the hot water braze plate and the hot water pump is at the top of the unit the pump gets air locked in some cause we have had to have the customer add a robust air eliminator such as a spirotop but always keep in mind it could leak or drip so where it is located be aware of that.

Hot Water Operation

If the lower tank temp is below the setpoint by more than the dead band temperature then the unit will start making hot water. If the upper tank is below the setpoint by more than ½ the dead band then it will start making hot water.

Now that all being said if the space demand is greater then the following conditions then the electric elements will kick in not the heat pump operation.

Noise From The Compressor

In the Hot Water mode there are times the compressor will make some chattering noises this is normal it is actually reed valves on the discharge of the compressor chattering.

Hot Water tank (Smart Tank)

Swapped thermistors we have seen this a few times you can see this with the service tool looking at the upper tank temperature and the lower tank temperature draw some hot water off in a sink if you see the upper tank temp showing its dropping right away would be a indication of these being swapped you would also see the lower tank not changing right away.

Leaky dip tube this will show up with the upper tank dropping right away along with the lower tank when drawing hot water off.

If the vacuum breaker is tightened correctly you can damage the o ring seal and cold water can enter the top of the tank.

Fault History

Diagnostics

Configuration

Last update: Thu Aug 01 2019 10:34 AM

| Diagnostic | Value | Units |
|----------------------------|-------|-------|
| Current Operating Capacity | 50 | % |
| ECM Blower Power | 44.5 | W |
| Output Status Flags 1 | 64 | |
| Output Status Flags 2 | 23 | |
| ECM Airflow Status | 755 | CFM |
| DHW Pump Status | 90 | % |
| Loop Pump Status | 24 | % |
| DHW Pump Flow Rate | 4.4 | GPM |
| Loop Pump Flow Rate | 2.4 | GPM |
| Compressor Target Speed | 27 | RPS |

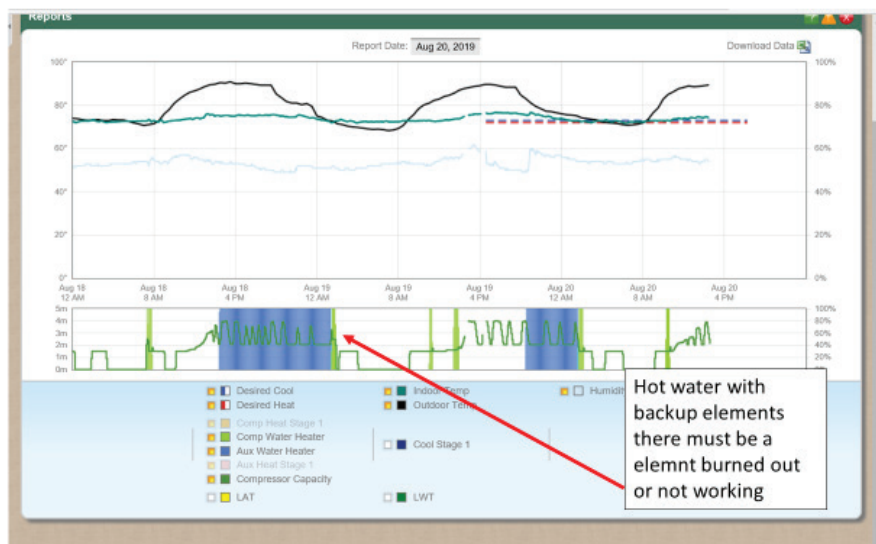

This was a case with a non working element the unit was trying to call for backup hot water but the element was not working. The reason it was trying to use the elements was because the units was set to 80% max cool you can see it was ramping there several times during this hot outside temps.

Setting back temperature of the space can cause not being able to make hot water with the QE unit and needing the back up elements to come on. Think about it when most might set back temperature at night and in the morning bring the temperature back up that is also when a lot of people are taking showers using hot water this will cause the QE to prioritize heating the space because of the large temperature difference and then use the back up elements in the hot water heater.

Setting back is not a good idea and if the customer does they need to be aware of this problem and it will more then likely cost them more then if they found a temperature they like and leave it.

This unit has some hot water issues because of restricted lines between the unit and the tank the piping is 64feet one way from the unit to the tank using 1" PEX!! The inside diameter of the 1" PEX is smaller then 1" copper and remember where the fittings go. Right now the unit at 50% Hot water operation is barely achieving a 9 degree delta T at 90% pump speed and 4.4 GPM. At times when the unit is in Hot water and cooling capacity can be higher then 50% all the way up to 80% when this unit is in Hot water and cooling and runs much above 50% this unit locks out on high pressure because of the low flow rate on the hot water side.

Zoning

Some things to think about with zoning that have caused some issues

Not setting the zone capacity properly for instance if you set a zone to say 500 cfm on a (1860) model that will only allow minimum capacity if that is the only zone calling if actually the load in that zone is greater then min capacity in this case 18,000 btu's then the unit will run and run and not satisfy that zone so proper CFM value that also relates to capacity is critical in the setup.

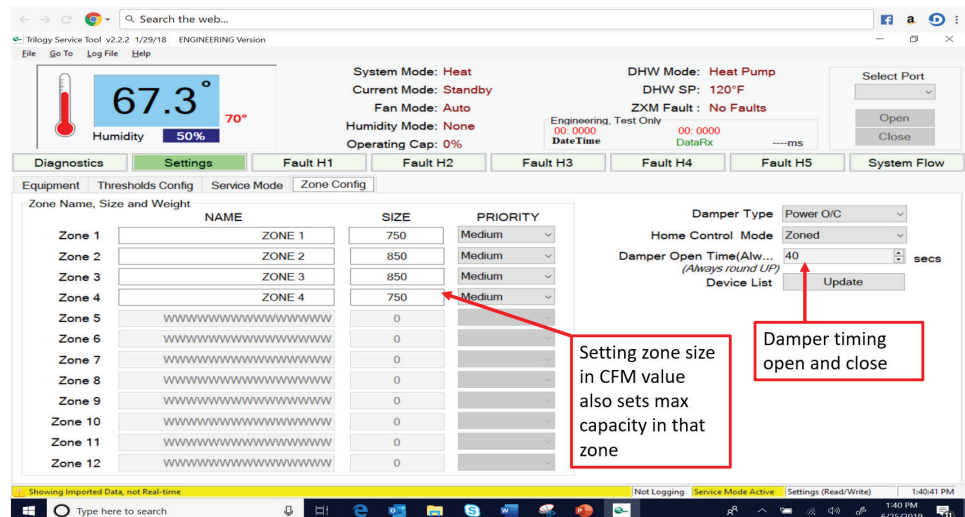

Example

Had a call the other day with a QE0930 with two zones close to the same size. When I received the call the unit was only running at 56% capacity and the complaint was the unit was not keeping up in either zone. After talking with the contractor and going through a few things I asked what was the two zone sizes that were set in the zoning tab he said they where both at 250CFM so the unit would not get over total of 500 CFM limiting the whole unit come to find out the zones could both handle 450CFM each so we moved them both to 450CFM and the unit immediately started to ramp up and then it was able to satisfy the point is it is really important to set these values correctly or this can happen to you and your customer.

Proper timing of the power open and power closed dampers is critical if the timing is off the control may think the damper is fully open but it may not be or not closed when it things it is and in that case it will over heat or cool that zone.

The zone board must have a secondary transformer sized for the number of thermostats and the dampers. The main lights on the ZXM will light up from the unit transformer but the dampers and the thermostats get power from the secondary transformer there is also a fuse on the board for this transformer.

With the original zone board software version in some cases with possible power issue or blips the thermostats will send out loss of communication faults (code 202) this version was 1.00 the latest version 1.01 fixes this issue and can be boot loader the software with the latest service tool version.

Communication errors

The biggest problem we see is poor connections be sure the field wiring to the EXM board where with the QE models we have wires doubled up be sure and do a tug test to be sure they are tight.

NO SPLICES this will cause communication errors

At the factory when the units are run tested on the EXM dipswitch number one is put into the off position for the test. IN the field this switch must be in the on position for communication.

These compressors use PVE oil what is the difference with PVE then POE

The inverter compressors in the QE and VE ClimateMaster product use PVE oil NOT POE oil.

Advantages of PVE (Poly Vinyl Ether Oil)

1. PVE oil is not Hydroscopic meaning it does not absorb water POE does.
2. Unsurpassed lubricity for greater wear protection
3. Compatible with all HFC refrigerants R410A

We do need to be careful and not mix POE oil with PVE oil when performing any refrigerant service on these units.

Sub assembly part numbers if needed for replacement parts.

EEV assembly's have the checks valves and copper tubes with some length to protect the components from excessive heat.

Braze plates heat exchanger with copper stubs to make it easier to replace and braze back in place.

Reversing valve assembly have copper tubing attached to make it easier.

Example EEV#2 assembly

How to read the performance charts and the operating charts from the IOM

Trilogy Troubleshooting Guide

Revised: March 23, 2020

These capacity % carry through all the different boxes KW, HE etc.

When verifying performance be sure to pay attention to the return air temp that you have it may make more since to verify the unit in heating even in the summer if the house is 71 degrees with low humidity. Otherwise in some cases when you compare the units data it may be off and you may begin to do further troubleshooting when the return air temp was the issue. In the product catalog there are conversion factors for different conditions I have also included in this document for reference.

Entering Air Correction Factors

| Cooling | | | | | | | | | | | | | |
|-------------------|----------------|---|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------------------|
| Entering Air WB°F | Total Capacity | Sensible Cooling Capacity Multiplier - Entering DB °F | | | | | | | | | | Power | Heat of Rejection |
| | | 65 | 70 | 75 | 80 | 80.6 | 85 | 90 | 95 | 100 | 100 | | |
| 50 | 0.734 | 1.046 | * | * | * | * | * | * | * | * | 1.017 | 0.770 | 0.853 |
| 55 | 0.811 | 0.871 | 1.062 | 1.240 | * | * | * | * | * | * | 1.017 | 0.837 | 0.896 |
| 60 | 0.890 | 0.666 | 0.876 | 1.073 | 1.257 | * | * | * | * | * | 1.013 | 0.906 | 0.932 |
| 65 | 0.957 | | 0.660 | 0.876 | 1.079 | 1.103 | 1.269 | * | * | * | 1.008 | 0.963 | 0.979 |
| 66.2 | 0.989 | | 0.604 | 0.825 | 1.032 | 1.056 | 1.227 | * | * | * | 1.002 | 0.990 | 0.991 |
| 67 | 1.000 | | 0.566 | 0.789 | 1.000 | 1.024 | 1.197 | 1.381 | * | * | 1.000 | 1.000 | 1.000 |
| 70 | 1.058 | | | 0.650 | 0.872 | 0.898 | 1.081 | 1.276 | * | * | 0.989 | 1.052 | 1.035 |
| 75 | 1.146 | | | | 0.635 | 0.663 | 0.862 | 1.077 | 1.278 | 1.466 | 0.969 | 1.166 | 1.101 |

* Sensible capacity equals total capacity.

| Heating | | | |
|-------------------|------------------|-------|--------------------|
| Entering Air DB°F | Heating Capacity | Power | Heat of Extraction |
| 50 | 1.052 | 0.806 | 1.114 |
| 55 | 1.042 | 0.852 | 1.090 |
| 60 | 1.030 | 0.901 | 1.063 |
| 65 | 1.016 | 0.951 | 1.032 |
| 70 | 1.000 | 1.000 | 1.000 |
| 75 | 0.983 | 1.046 | 0.967 |
| 80 | 0.966 | 1.087 | 0.935 |

AHRI/ISO/ASHRAE 13256-1 uses entering air conditions of Cooling - 80.6°F DB/66.2°F WB, and Heating - 68°F DB/59°F WB entering air temperature
